This report constitutes a user's manual for "FLYIT3", a 3-degree-of-freedom trajectory simulation program written in FORTRAN IV. The three degrees of freedom are range, altitude, and pitch attitude.

The program is useful in simulating vertical-plane trajectories involving take-offs, climbs, cruises, dives, landings, and rocket boosts. The program is particularly well suited to the synthesis and analysis of air-to-surface and surface-to-surface missiles (especially cruise missiles) and aircraft trajectories.

INTRODUCTION

"FLYIT3" is a 3-degree-of-freedom trajectory simulation program written in FORTRAN IV. The three degrees of freedom are range, altitude, and pitch attitude. Pitch attitude (or angle-of-attack) is a pseudo degree of freedom, in that its rate of change is unaffected by the mass properties of the vehicle. In this respect, the vehicle is treated as a particle, the forces acting on which are controlled by its attitude, among other things.

The program is useful in simulating vertical-plane trajectories involving take-offs, climbs, cruises, dives, landings, and rocket boosts. The program assumes that the earth's surface is "flat," in that no force is applied to the vehicle (other than gravity) to prevent growth of the altitude coordinate as the range increases. The program is particularly well suited to the synthesis and analysis of air-to-surface and surface-to-surface missiles (especially cruise missiles) and aircraft trajectories. FLYIT3 should be used for preliminary study only. It is not suitable (due to its ignorance of rigid-body effects, primarily) for air-to-air trajectories, terminal engagements, 2-body problems, or altitudes over 100,000 feet MSL. This manual is written, in part, to familiarize the user with FLYIT3's limitations as well as its capabilities.

FLYIT3 is easy and inexpensive to use, is compatible with batch and demand terminals, and at NWC can automatically produce a plot of any trajectory. The program is simply structured, permitting a user to expand, contract or alter its capabilities. In most cases, the user must, in fact, provide his own coding to describe his vehicle's aerodynamic and propulsion characteristics. However, this manual provides comprehensive guidance in this area. No coding need be provided by the user to "control" the trajectory. Such control is provided by careful selection of the input data. All known "bugs" in the program have been eliminated (although it is not guaranteed that there are none). In most cases of difficulty, the content or format of the input data is at fault.

This manual assumes the reader's familiarity with FORTRAN and the UNIVAC 1110 executive system. Operation is described in terms of demand terminal usage, though batch mode is no less compatible.

NWC TM 3540

ACCESS TO THE PROGRAM

At NWC, FLYIT3 is stored in the read-only file FLYIT*3. The program is also stored in a file of the author and as a card deck. Users must copy FLYIT*3 into their own files (permanent or temporary) before use. A minimum of 200 tracks should be assigned to the file to permit additions or alterations to be made to the program in the user's file. In case of difficulty, contact the author or inquire of the Propulsion Analysis Branch, Code 3241.

STRUCTURE OF FLYIT3

The source program is written in FORTRAN IV. Execution and flow-of-control is performed by the main program element, FLYIT3. The main program calls subroutines from other functional groups as needed to supply data with respect to aerodynamics, propulsion, etc. The functional groups are: atmosphere, trajectory controls, aerodynamics, rocket boosters, and sustain propulsion. Each of these groups contains several subroutines, one or more of which is generally used for each trajectory. Each subroutine is (has been) compiled into a binary relocatable element with the same name as its symbolic source element.

The file FLYIT*3 contains a runstream element titled FLYIT*3. REASSEMBLE. As the name suggests, this element is @ADDED to MAP the relocatable elements into an executable element named EXECUTABLE. REASSEMBLE need not be used unless a source program element has been altered and recomplied since the last run.

Another runstream element, DATA, is @ADDED to execute the program. DATA contains the data describing the vehicle, the trajectory to be flown, and the output format. In addition, DATA contains instructions to describe the trajectory plots to be produced, if desired. FLYIT3 uses NWC's SHOMAT plotting program to produce plots at minimum cost. See sections titled "DATA" and "PLOTTING."

Each functional subroutine group is described in some detail in the following sections.

MAIN PROGRAM: FLYIT3

Subroutine FLYIT3 is listed in Appendix A. It begins with condensed input instructions to the user in the form of comment lines. Upon

execution (@ADD FLYIT*3.DATA) this subroutine informs the user it is ready to read data by printing "enter data." The data is then read (3 lines) from the runstream element DATA without further interaction with the user. FLYIT3 then establishes the output format based on the data received. Initial conditions are established, also based in part on the input data. When certain output options are specified in the data, FLYIT3 prints the input and output data. Input options are discussed under "DATA" below. Next, FLYIT3 enters four nested DO loops within which the trajectory is simulated. The outer loop in effect defines a limit on the number of "pages" of output printed, via a "max time" limit. The next loop limits the number of output lines printed to 46, at which time new output column headings are printed and output printing may continue. On demand terminals, this results in page-length segments of output suitable for binding. On batch printers, the new output headings are printed at the top of a new page. The next loop controls the print interval in terms of the number of iterations calculated before a line of output is printed. The innermost loop controls the frequency with which new atmospheric properties are calculated. (This feature saves time and cost under conditions where atmospheric properties change slowly or not at all.)

FLYIT3's next move (within the innermost loop) is to call one of three atmosphere subroutines, ATMSTD, ATMHOT, or ATMCLD (if required). These subroutines supply to FLYIT3 the properties of standard, hot-day, and cold-day atmospheres.

The next step is to call one of the subroutines M1, M2, M3...M10, which selects the vehicle angle-of-attack required to fly the desired trajectory. In some cases, the M-subroutines in addition constrain accelerations, flight path angles, altitudes, etc. when required. The subroutine called in this group depends on the value of the variable MGO. MGO is always equal to the subscripted variable M(MM). The subscript MM is the position in a data string of the desired sequence of trajectory segments. Each value of M() from 1 thru 10 in the data string corresponds to a particular mode of flight (climb, dive, cruise, etc.). The modes indicated by M() are briefly described below:

- M=1 Runway take-off at max power from field elevation XLH.
- M=2 Air launch at XLH altitude, XLMN Mach, XLFEEC flight path angle, and climb at CLMN Mach DFEEC flight path angle and continuously reduce flight path angle if necessary to maintain speed.
- M=3 Cruise at DCH altitude and CMN Mach until RC range is reached or fuel is exhausted.
- M=4 Dive at -DFEEDD flight path angle until pull-up is initiated.
- M=5 Pull-out from dive at GPU load factor and cruise at DTH altitude and DMN mach.
- M=6 Fly at constant velocity until DCH altitude or RC range is reached or impact.
- M=7 Launch with flight path angle DFEEC first 100 feet.
- M=8 Fly at body angle BAC or BAD degrees until DCH is reached.

M=9 Approach to landing at glide slope DFEEDD, runway elevation DTH, approach speed DMN Mach.

M=10 Directs the vehicle to fly along the radar horizon when the horizon is intercepted in M=3 cruise. Target antenna is assumed to be at 100 feet above sea level. Range to target must be input as RC (nmi).

If used at all, M=1 and M=7 must be first in the sequence.

If used at all, M=9 will be last in the sequence.

No M value may be used more than once in a trajectory except M=2, 3, 4, 6, 8.

M=4 must be used in the sequence 45, or be the last in the sequence.

M=10 if used at all must be last in the sequence.

(The above was excerpted from the input instructions contained in FLYIT3.) A typical data string (included on the first of the three lines of input data) might be 1834560000. In this case, M(1)=1, M(2)=8, M(3)=3, etc.; other input data indicates cruise altitudes, climb and dive angles, Mach numbers, etc. for each segment (M value) in the trajectory. Input data is discussed in detail under "DATA" below.

Upon receiving commands from the trajectory controls group, FLYIT3 calls for vehicle aerodynamic characteristics from the aerodynamics group, subroutines AERO1, AERO2... AERO15. The subroutine called is indicated by the input data value NAERO. For example, if NAERO is 12, AERO12 will be called. The user is responsible for the contents of AERO12, or whichever subroutine he uses. Fifteen AERO subroutines are provided so that each user's file may constitute a library of aerodynamic characteristics, any of which may be selected by a simple change in the data value NAERO. The same discussion applies to the boost propulsion group and sustain propulsion group, discussed below.

FLYIT3's next call is to the booster propulsion group, subroutines BSTR1 thru BSTR15. The controlling input data value is NBSTR. If NBSTR is blank, zero or negative, a booster is assumed to be absent throughout the trajectory. If a booster is used, the user is responsible for supplying its thrust-time profile, specific impulse, burnt weight (which will be automatically "dropped" at the end-of-boost), and incremental aerodynamics, within the subroutine he uses.

FLYIT3 then calls for sustain propulsion information from subroutines SUST1 thru SUST15. Again, the user is responsible for the contents and selection of these subroutines. The controlling input data value is NSUST. Twenty subroutines are available. If no sustainer is present, NSUST must be blank, zero, or negative. If a sustainer is used, the input data value W0 (launch weight) must be greater than the input value WE (empty weight). The difference in these values must include sustain fuel or propellant and booster weight. The sustainer subroutines must set sustain thrust equal to zero when the vehicle weight W becomes less than the empty weight.

GROSS FUELLED MISSILE WEIGHT, INCLUDING BOOSTERS 1400.0 POUNDS
 MISSILE EMPTY WEIGHT, WITHOUT BOOSTERS 1000.0 POUNDS
 DRAG AND LIFT REFERENCE AREA 1.000 SQUARE FEET
 DESIRED CLIMB ANGLE TO CRUISE ALTITUDE 25.0 DEGREES
 DESIRED CLIMB MACH NUMBER, IF APPLICABLE 1.50
 DESIRED CRUISE ALTITUDE 15000. FEET (TO 50. MILES RANGE)
 DESIRED CRUISE MACH NUMBER 1.70
 DESIRED DESCENT ANGLE FROM CRUISE ALTITUDE -10.0 DEGREES.
 DESIRED DESCENT MACH NUMBER .900
 DESIRED DASH ALTITUDE 100. FEET (MACH .90)

FIG. 1. Full-list Output Data Format.

NWC TM 3540

FLYIT3, with all the information thus obtained from subroutine calls each iteration, calculates the vehicle accelerations, velocities, and positions. If the altitude becomes negative or exceeds 105,100 feet MSL, or the Mach number exceeds 5.6, the program will terminate. Range and altitude values are stored for subsequent plotting and output data are printed at selected iteration intervals. The iteration time interval is normally 0.25 second, but is reduced during boost (0.025) and during periods of maneuvering, and lengthened (to 0.5 second) during cruise. Finally, when the trajectory has been calculated to completion, FLYIT3 calls the SHOMAT (Ref. 1) plotting program if plots have been requested by the input data.

FULL-LIST OUTPUT: OUTPT1

OUTPT1 is a subroutine used to print a detailed summary of the input data (Figure 1). This format is not normally used for routine demand terminal work. The alternative output format for listing the input for each trajectory is defined and printed by:

```
7234560000      1   0   1   1   4   5   0   0
1400. 900. 1.00 15. .47 1.00 5.0 .01 .00 .0

STANDARD ATMOSPHERE
```

FIG. 2. Demand-Mode Output Data Format.

ATMOSPHERES

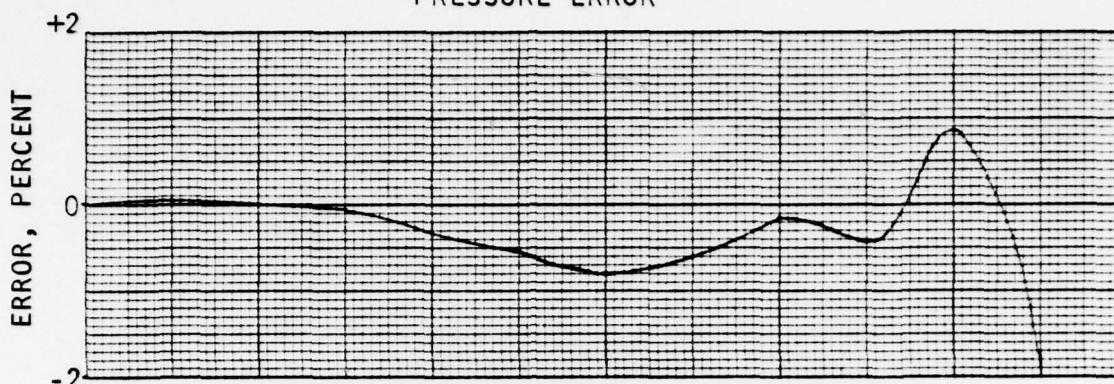

ATMSTD

Subroutine ATMSTD generates air temperatures and densities in accordance with the U.S. Standard Atmosphere, 1962. The densities calculated are in error less than 0.1 percent below 36,152 feet MSL and less than 1.0 percent from 36,152 feet to over 120,000 feet. (See Figure 3). The temperatures calculated are in error by less than 0.05 degree R up to 105,000 feet MSL. Pressure is calculated from density and temperature in subroutine FLYIT3. The resulting pressure is in error by less than 0.9 percent up to 108,000 feet MSL. Atmospheric properties are most accurate in the troposphere, where most trajectories are flown.

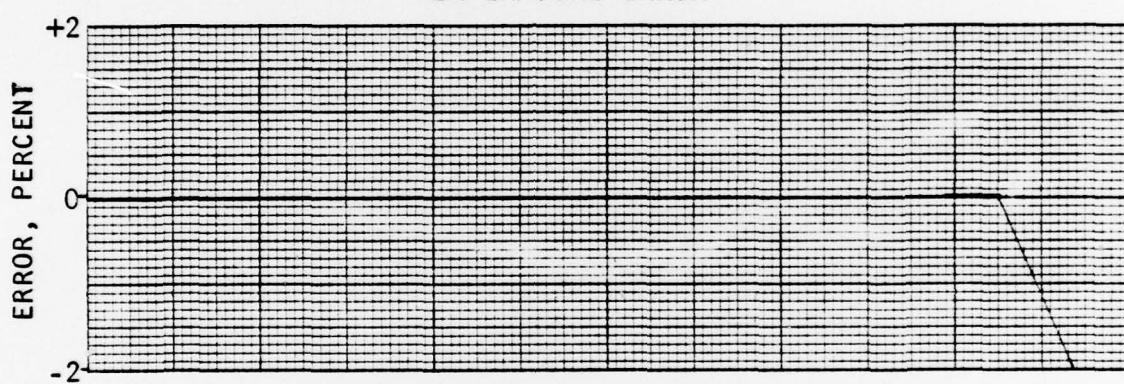

ATMHOT

This subroutine supplies air data in accordance with the MIL-STD-210A Tropical Atmosphere. No error analysis has been done on this model, but errors should not exceed 2 percent or 0.2 degree R up to 100,000 feet.

PRESSURE ERROR

TEMPERATURE ERROR

DENSITY ERROR

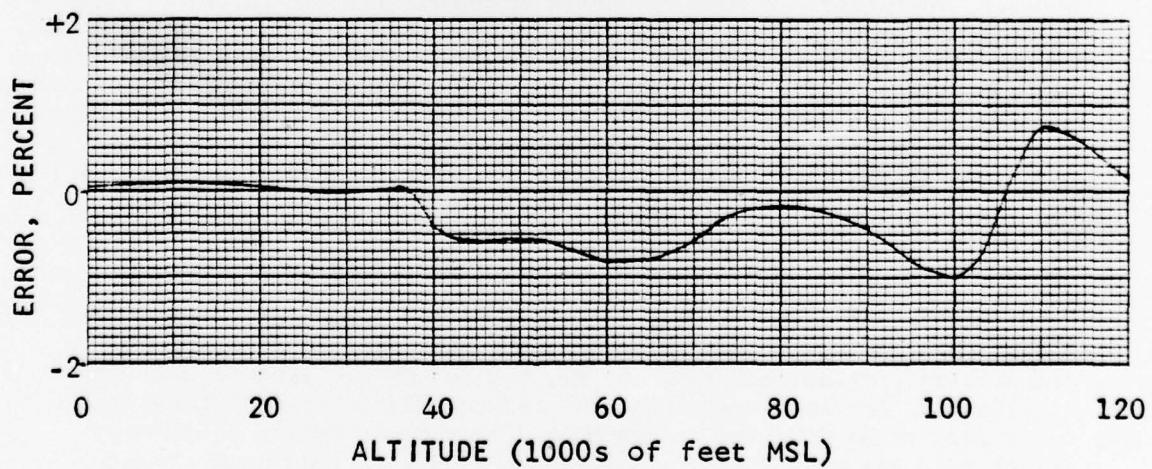

Figure 3. Standard Atmosphere Model (ATMSTD)
Deviation from 1962 U.S. Standard Atmosphere.

ATMCLD

This subroutine supplies air data in accordance with the MIL-STD-210A Polar Atmosphere. Densities and pressures are accurate to 1.0 percent below 40,000 feet, but accuracy diminishes at higher altitudes. Temperatures are accurate within 0.2 degree R.

ATMSTD, ATMCLD, and ATMHOT are listed in Appendix C.

TRAJECTORY CONTROLS

The M1, M2, . . . M10 subroutines control the trajectory shape in accordance with the user's data entries, and are thus the real heart of the program. The logic and flow of control within these subroutines is quite complex and the user is cautioned against casual tampering. The user is advised to become familiar with this section and the section titled "DATA" before attempting to use the program. It is surprising, even to the author, what a wide variety of trajectories is capable of being simulated by FLYIT3 with judicious choice of input data. Numerous examples are displayed in Appendix I. The M-subroutines are listed in Appendix D.

M1

This subroutine simulates a runway take-off. Propulsion can be booster, sustainer, or both in series or parallel. The runway is assumed to be level and its elevation above sea level is the input data value XLH, in thousands of feet. Liftoff occurs when the airspeed reaches 1.20 times the airspeed at which lift would equal weight at the angle-of-attack limit, specified by the input data value ALPL (degrees). At the time of liftoff, control of the trajectory is transferred to the next M-subroutine as indicated in the input data sequence M(1), M(2),...M(10).

M2

The M2 subroutine is used for climbing and diving at a specified flight path angle. M2 can be used as the first in the M-sequence to simulate an air-launch. (M4, M6, M7, M8, and M9 can also be used for air-launch. For any air-launch, the launch altitude is specified by the input data value XLH, the launch Mach number by XLMN, and the launch flight path angle by XLFEE. "Air-Launch" could include cases in which prior to "time zero" there occurred a boost phase, catapult launch, ordnance release, etc. In this way, a complex trajectory can be pieced together. The capability of FLYIT3 rarely requires piecing, however.)

The flight path angle at which the climb or dive is to proceed is entered as the input data value DFEEC (degrees from horizontal). In addition, a climb Mach number can be entered as data (CLMN), which sustain propulsion can be throttled to maintain (if the user's propulsion subroutine is so programmed). In M2, if the propulsion is unable to maintain the specified climb angle, the climb angle will be progressively lowered so as to maintain approximately constant Mach number (to prevent stall or "mushing").

M2 (also M8) anticipates arrival at some cruise altitude (DCH) during the climb. The vehicle is caused to initiate a ballistic (zero-lift) turn-down at approximately the time which permits arrival at the cruise altitude at a flight path angle of zero. M2 transfers control to the next M-subroutine in the M-sequence when fuel is exhausted, range exceeds the input data value RC (nautical miles), or cruise altitude is reached. If the flight path angle is reduced to essentially zero, the transition (usually to M3) will be made and DCH redefined as the present altitude.

M3

M3 provides for cruising at altitude DCH and Mach number CMN. Stable altitude-hold is achieved by the use of an equation which represents a proportional feedback control system. Two error signals are used, altitude itself and the flight path angle. Damping is provided by mixing the required angle-of-attack with the one used in the previous iteration. The user is cautioned against changing the gains and coefficients in the altitude-hold equation, as they have been optimized with respect to a broad spectrum of vehicles and trajectories over many years of use.

The M3 cruise leg of a trajectory is normally terminated by either of two events. The first is the attainment of a range specified as input data value RC (nautical miles). The second is fuel exhaustion (current vehicle weight less than vehicle empty weight (WE) pounds in data). When M3 is terminated, trajectory control is transferred to the next M-subroutine in the M-sequence.

M3 can be used as an acceleration leg of a trajectory, if that leg is to be followed by another cruise leg at a higher altitude. In this case, M3 terminates when the Mach number CMN is attained in level flight. The second M3 leg will be flown at a Mach number of CLMN +0.5. This feature is useful when a speed much higher than the launch speed is required for good climb performance to a higher altitude.

If M3 is to be followed by an M6 climb, the climb will be initiated when the Mach number exceeds CLMN. M6 will then maintain this approximate Mach number - see under M6.

M4

M4 is used for diving at constant flight path angle. M4 is useful for flying a transition from a cruise altitude to a lower cruise altitude (see M5), for dives to impact (...40... in the M-sequence), and for line-of-sight trajectories (e.g., WALLEYE). The diving flight path angle is entered in the data as DFEEDD (degees, positive for dives). Climbs can also be performed by M4 by entering a negative value for DFEEDD; however, a smooth transition to the next M-subroutine in the sequence cannot be assumed. (An M4 climb would be useful for simulating a "zoom;" for example, just prior to a parachute deployment, to lower the airspeed.) The input data value DVMN provides for a Mach number to be maintained in the dive by means of propulsion throttling.

Flight path angle is sought and maintained (following a ballistic turn-down) by a proportional feedback control system equation which uses flight path angle as the error signal and angle-of-attack mixing as a damping term. In dives, M4 is terminated by impact (attainment of zero altitude) or by arrival at a altitude at which a pull-up must be initiated for transition to an M5 cruise leg.

M5

M5 provides for a low level cruise (dash) leg and the pull-up thereto. Transition to M5 can be made only from M4 (M5 is also used by M9 and M10). The altitude for this dash leg is input as DTH (thousands of feet MSL), and the Mach number as DMN. If DTH has the same value as DCH, the M-sequence ...345... can be used to properly transition (smoothly) from M3 to M5 without significant disturbance of altitude. This sequence is useful for flying a constant-altitude trajectory with a change in speed at RC range from launch.

M5 provides stable altitude hold in the same way as does M3.

The pull-up from dive to level flight is controlled such that the maximum normal load factor is GPU g's, the angle-of-attack limit ALPL is not exceeded, and the maneuver is initiated (usually) in time to prevent substantial undershoot of DTH. Some combinations of dive angle, speed, throttling, aerodynamics, and DCH cause enough undershoot that sea level impact threatens the trajectory. In this case, the angle-of-attack is increased so as to produce load factors greater than GPU in the interest of salvaging the simulation. To avoid this problem, it is recommended that DCH values of less than 0.1 (100 feet MSL) not be used. The impact of this restriction on simulation results is negligible, considering the typical accuracies represented by propulsion and aerodynamics models.

M5 is terminated only by fuel exhaustion, at which time a transition is made to the next M-subroutine in the M-sequence.

M6

The M6 subroutine flies an approximately constant speed trajectory, holding the speed at which transition into M6 is made. However, the speed is maintained by continuous adjustment of the flight path angle rather than throttling the propulsion. This mode of flight is suitable for launch, climbs and dives, and cruise. When the altitude range is small, this mode simulates constant pitch trim. Transition out of M6 can be caused by a number of occurrences, such as range exceeding RC, DCH being reached, etc.

M7

M7 provides for air- or surface-launch in which the direction of motion is fixed for the first 100 feet of travel (rail launch). This option, which must be first in the M-sequence if used, is convenient for low-speed or zero-speed launches with or without booster. It eliminates the otherwise troublesome problems of launcher tip-off and lack of aerodynamic control and lift at low speeds.

M8

Subroutine M8 provides a means of climbing and diving which is well suited to traversing wide spans in altitudes. The flight mode is one of a constant pitch attitude with respect to the horizontal. Two pitch angles are input, BAC (body angle for climbs) and BAD (body angle for dives). This mode of flight is one typically used by a pilot flying an aircraft, even if he is not consciously aware of using it. It is equivalent to maintaining a fixed line of sight between the pilot's eyes, some reference point on the aircraft (speck on the windshield, nose highlight, etc.), and the horizon. For fixed thrust, the equivalent airspeed (EAS) will be approximately constant. Flight at constant body attitude is relatively easy to mechanize in an airframe control system, since the only sensor required is a single-axis gyroscope. In constant attitude flight, the angle-of-attack, airspeed, lift, drag, and flight path angle vary in an inherently stable manner. The result, in an atmosphere whose density decreases with altitude, is a tendency for the flight path angle to smoothly approach zero and the speed to increase as high altitudes are approached. The tendency for flight path angle to increase or decrease depends also on the throttle setting and the actual body angle selected. The user will want to try different values of BAC and BAD for each vehicle configuration in order to achieve suitable climb/dive performance (i.e., proper variation of speed with altitude).

M8 will decide, based on the altitude with respect to DCH at the time of transition to M8, whether BAC (climb) or BAD (dive) is appropriate. If fuel exhaustion occurs while M8 is active, M8 will fly at BAD to impact. Otherwise, M8 will fly at BAC or BAD so as to approach DCH. However, if M3 has previously been active in the trajectory or an M2 climb has immediately preceded current M8 activity, M8 will seek DTH. If M3 is the next indicated subroutine in the sequence, but the range exceeds RC while M8 is active, control is transferred to M3 at that time. (Subsequently, M3 will immediately transfer control to the next M-subroutine in the sequence.) When climbing toward DCH, M8 will anticipate arrival and initiate a ballistic turn-down as in M2.

M9

M9 provides for simulating a final approach to a runway landing and the subsequent roll-out with braking. The runway elevation is input as DTH, the glide path angle is DFEEDD (positive), and approach Mach number DVMN. The user should provide suitable aerodynamics and propulsion for the landing configuration (i.e., flaps and wheels down). To account for braking after touchdown, the user must insert a coefficient of rolling friction (retarding force/weight) into subroutine FLYIT3. The variable name for this coefficient is FRIC, and is defined as a constant (0.5) among the initial conditions of FLYIT (line 120, approximately). The user must edit and recompile FLYIT3 whenever FRIC is redefined.

M9 will print a line of output indicating the time of touchdown and the touchdown flight path angle. This angle is different from the glide path angle, because a 1.1-g flare occurs prior to touchdown. Another output line is printed when the vehicle rolls to a stop, indicating the total runway length used.

When M9 is indicated in the M-sequence, it must be followed by a zero, and must not be preceded by 45.

M10

Subroutine M10 causes the vehicle to follow a path coincident with the radar horizon with respect to a target. The range from launch point to the target must be input as RC (nautical miles). The target's radar antenna is assumed to be 100 feet above sea level. The transition to M10 must occur from M3 cruise.

The radar horizon path is tangent to the sea surface 12.28 NM from the target. Since the vehicle cannot be expected to fly at zero altitude, it is caused to level off and cruise at 100 feet MSL when the altitude drops to 100 feet. At this time M10 redefines DTH = 100 (feet), and causes a transfer of control to M5. Depending on the user's propulsion coding, the vehicle can be flown at Mach numbers of DVMN or CMN in the descent, and DVMN, CMN, or DMN (among others) in the final cruise leg.

The trajectory will terminate in M10 when the range to target becomes zero. M10 will print the time-to-target and range flown at impact.

AERODYNAMICS: AERO1 THRU AERO15

Subroutines AERO1 thru AERO15 are available to the user to define his vehicles' aerodynamic characteristics. The file FLYIT*3 includes AERO1, AERO2, and AERO3 as real, text-contained elements which serve as examples of satisfactory coding, in addition to possibly being useful to the user. (See Appendix E for listings.)

Each AERO subroutine must provide values for the following variables in the common block:

CDO - zero-lift drag coefficient,
CDI - induced (or drag-due-to-lift) drag coefficient,
CL - lift coefficient (not normal-force coefficient), and
CLAR - the rate of change of CL with angle of attack in radians
(lift-curve slope).

All these coefficients are to be based on the input data value AREF, the aerodynamic reference area in square feet.

In order to calculate these variables, the AERO subroutines may use any of the variables in the common block of FLYIT3. Most typically, these are:

M(MM)	- the active M-subroutine (or MGO),
W	- vehicle weight,
RO	- atmospheric density,
ALPHA	- angle-of-attack in degrees,
ALPL	- angle-of-attack limit in degrees,
V	- true airspeed in feet per second,
Q	- dynamic pressure in psf,
H	- altitude in feet MSL,
AMACH	- Mach number, and
AC	- inlet capture area in square feet.

The basic aerodynamics can be modified by the user's propulsion subroutines. This is usually the most convenient way to increment zero-lift drag to account for detachable boosters, inlet spillage drag, and engine cold-flow drag.

NWC TM 3540

Subroutine FLYIT3 adds the basic AERO-produced and incremental characteristics and calculates the lift and drag forces.

ROCKET BOOSTERS: BSTR1 THRU BSTR15

Subroutines BSTR1 thru BSTR15 are available to define the characteristics of rocket boosters which may be used on a vehicle. The file FLYIT*3 includes BSTR1, BSTR2, and BSTR3 as real, text-containing, unclassified, elements which serve as examples of satisfactory coding, in addition to possibly being useful to the user. (See Appendix F for listings.) Many booster motors have been modelled by and are available from Code 3241.

Each BSTR subroutine must provide values for the following variables in the common block:

THR	- booster gross thrust in pounds (assumed to be aligned with the angle-of-attack datum, usually the fuselage axis),
FISPB	- propellant specific impulse in lbf-sec/lbm,
DT	- iteration time interval during boost (this value overrides values established by the M-subroutines - 0.025 is recommended),
EWB	- the weight dropped at end-of-boost in pounds,

Any other variable in the common block can be modified by or used by BSTR. These typically include:

TIME	- time accumulated since launch in seconds,
CDO	- zero-lift drag coefficient (usually incremented by the additional drag of the booster),
H	- altitude in feet MSL (used to augment booster thrust and Isp with altitude).

The input data value NB permits multiple boosters to be used on one vehicle, on the assumption that all boosters are ignited simultaneously.

SUSTAINER PROPULSION: SUST1 THRU SUST20

Subroutines SUST1 thru SUST20 are available to define the characteristics of sustainers. The file FLYIT*3 includes SUST1 thru

SUST4 as real, text-containing, unclassified elements which serve as examples of satisfactory coding, in addition to possibly being useful to the user. (See Appendix G for listings.) Other sustainer engines have been modelled and are available from Code 3241.

Each SUST subroutine must provide values for the following variables in the common block:

THRS	- sustainer thrust in pounds
FISPS	- sustainer propellant specific impulse
CDAOFF	- additional zero-lift drag coefficient resulting from an engine-off condition (must be referenced to AREF)

Any other variable in the common block can be modified by or used by SUST. These typically include:

H	- altitude,
AMACH	- Mach number,
RO	- atmospheric density in slugs/ft ³ ,
ALPHA	- angle of attack,
Q	- dynamic pressure in psf,
DT	- time increment,
TM	- sustainer thrust multiplier (see below),
AC	- inlet capture area for unit value of TM in ft ² (see below),
CMN	- desired cruise Mach number,
CLMN	- desired climb Mach number,
DVMN	- desired dive Mach number,
DMN	- desired dash Mach number,
PT	- freestream total pressure in psia,
TT	- freestream total temperature in °R,
AMACH1	- flight Mach number prior to last iteration,
THR	- booster thrust,
T	- ambient air temperature in °R, and
MGO	- M-subroutine currently active.

The input variable TM is a sustainer thrust multiplier. This variable permits the sustainer and its inlet to be conveniently scaled in thrust. If TM = 1.0, the engine will produce the performance coded in SUST. If TM is different from unity, the thrust and inlet capture area will be scaled by TM.

Each sustainer subroutine must contain the performance of an inlet, if applicable. Inlet additive and spillage drag is usually added to CDO in SUST; however, the variable CDAOFF is available as an incremental zero-lift drag coefficient which is added to CDO in subroutine FLYIT3.

The variables ASPEED and TIT (for gas turbines, rotor speed and turbine inlet temperature, respectively) may be used as diagnostic or informative parameters. They are printed as output data in the batch (full list) output format.

The SUST subroutines are responsible for setting THRS = 0.0 if and when the vehicle weight W becomes less than the empty weight WE.

Rocket motors may be modelled as sustainers as well as boosters; however, the coding is not directly interchangeable between BSTR and SUST.

Contractor-supplied engine performance coding can be integrated into or called from a SUST subroutine, but proper interface coding must be provided.

SUST is responsible for engine throttling if this feature is desired. The input variables CMN, CLMN, DMN, and DVMN in conjunction with MGO, AMACH, and AMACH1 indicate whether an increase or decrease in thrust is desired. In simple throttling equations, it is recommended that a proportional control system with damping be used. The quantity (DMN-AMACH), for example, would be the error signal and the rate-of-change of Mach number ((AMACH-AMACH1)/DT) would stabilize the system. To approximate the response time of a real sustainer engine, a limit could be imposed on the rate of change of a critical engine parameter (e.g., rotor speed). The throttling equations can range from no throttling at all to a full digital simulation of a complex fuel control system.

The author disclaims responsibility for the accuracy of models contained in FLYIT*3 representing real engines, existing or proposed. Code 3241 has available coded models of many engines.

REASSEMBLE

Element REASSEMBLE is a runstream element which when @ADDED maps the relocatable elements in FLYIT*3 and the library file PLT*PLOT&LIBRARY into an executable program element named EXECUTABLE. REASSEMBLE should be @ADDED prior to the user's first run attempt and after any source elements in FLYIT*3 have been edited and recompiled (except for element DATA, which is a runstream element and is not complied). FLYIT*3 should be @PACKed following each new MAPping, to prevent a storage overflow. REASSEMBLE is listed in Appendix H.

DATA

Element DATA is a runstream element which causes the absolute program EXECUTABLE to be executed, and which contains the input data for the run. DATA also contains plotting instructions for the SHOMAT plotting program. A successful example of DATA is listed in Figure 4. Line numbers (1 thru 18) have been included for reference, but are not part of the text of DATA. Line 1 causes EXECUTABLE to be executed. Lines 2, 3, and 4 constitute the input data itself (see discussion below). Lines 5 thru 17 constitute instructions for SHOMAT plotting. If no plotting is desired, lines following line 5 are ignored and can be omitted. Line 18 (@EOF) is necessary only when plotting instructions are used. It signals the end of the plotting instructions and causes the plotting to be executed one trajectory per page. (@EOF replaces @FIN as discussed in Reference 1.) The user is referred to Reference 1 for detailed instructions on the use of SHOMAT.

FIGURE 4. A Successful Version of Element DATA.

INPUT DATA (LINES 2, 3, AND 4)

Lines 2, 3, and 4 are reprinted and dissected in Figure 5 for illustration. Refer to the section on trajectory controls for supplementary descriptions of the functions of each variable. When constructing or editing lines of data, pay strict attention to the field allotments (spacing). Floating point data should have decimals punched. Line 2 should contain no decimal points. In the short-form output data format such as appears in Figure 2, and in the examples of Appendix I, DATA lines 1, 2, and 3 are repeated as output in a similar format.

Line 2: The format is (10I1,8I5). The first ten fields are the M-sequence which indicates qualitatively the trajectory shape and modes of flight. (Lines 3 and 4 contain values which quantify the trajectory and the vehicle.) The M-sequence is discussed in detail under "Trajectory Controls" above. The next field contains the variable NB, the number of booster motors used in parallel. This number is meaningless unless a booster unit is specified by the variable NBSTR. The next field contains the variable NATM. A blank or zero specifies the use of the ATMSTD atmosphere model for the run, "1" calls for Topical Atmosphere (ATMHOT), and "2" calls for Polar Atmosphere (ATMCLD). The next field contains the variable NAERO, which is the aerodynamics subroutine to be used; i.e., "1" calls AERO1, "2" calls AERO2, etc. The next field contains NBSTR. "1" calls subroutine BSTR1, "2" calls BSTR2, etc. The next field contains NSUST. "1" calls SUST1, "2" calls SUST2, etc. The next field contains the variable NOUTPT. The allowable options are 0, 1, 2, 3, 4, and 5. "0" or blank specifies the 132-column output format (Figure 6) (batch-mode) with a short-form listing (Figure 2) of the input data. "1" specifies batch-mode output format (Figure 5) with input data fully described by the full-list format (Figure 1). "2" specifies option "1" plus a plot of the trajectory. "3" specifies the 70-column demand-mode output format with a full-list description of input data. "4" specifies the short-form demand-mode output format (Appendix I). "5" specifies option "4" plus a plot. The next field contains NPRT. If a positive number is placed in the field, the trajectory output data will be printed four times more frequently than usual, allowing a "closer look" at maneuvers, boost phase, etc. The last field contains NFEET. If a positive number is in this field, the range output will be in feet. Use this option only for a short-range trajectories.

Line 3 (Format 10F5.0): The first field contains W0, the loaded (launch) weight of the vehicle, including fuel, boosters, etc. The second field contains WE, the vehicle empty weight, without usable fuel, dropables, etc. Weights must be in pounds. The third field contains AREF, the aerodynamic reference area, in square feet. The fourth field contains the angle-of-attack limit in degrees. The program does not use negative angles of attack, and a lower limit of 0 degrees is assumed. The fifth field contains AC, normally the inlet capture area in square feet per sustainer engine of unit size. AC is automatically scaled by

NWC TM 3540

the input data value TM. AC may be used for another purpose if inlet capture area has no bearing on the trajectory, since it is included in the common block. The sixth field contains TM, the thrust multiplier or sustainer engine scaler. TM scales the sustainer thrust, inlet drag, airflow, etc. The seventh field contains GPU, the normal load factor used for pull-up maneuvers performed in M5, in g's. The last three fields contain the launch parameters XLH (launch altitude), XLMN (launch Mach number), and XLFEE (flight path angle above horizontal), respectively. All input altitudes are in thousands of feet MSL, and all input angles are in degrees.

Line 4 (FORMAT 11FS.0): The first field contains DFEEC, the desired or initial climb flight path angle for use by M2 and M7. The second field contains CLMN, the desired climb Mach number for use in M2. If the M-sequence begins 2383..., attainment of CLMN in the first occupation of M3 will trigger transition to the M8 climb. The third field contains BAC, the vehicle body angle to be used for climbs in M8. The fourth field contains BAD, the body angle to be used for M8 dives. The fifth field contains DCH, the desired cruise altitude. This altitude will be sought during the first climb or dive if 3 is included in the M-sequence. The sixth field contains CMN, the desired cruise Mach number, for use in M3. The seventh field contains RC. This is the range in nautical miles which, when attained, causes a transition to the next M-subroutine in the M-sequence. Normally RC triggers the end of cruise. When the M-sequence includes ...310..., RC is assumed to be the distance from launch point to target. The eighth field contains DFEEDD, the desired flight path angle for use in M4 and M9. For dives and landing approaches, positive values should be used. The ninth field contains DVMN, the Mach number sought in M4 and M9. The tenth field contains DTH, the altitude to be sought and held for cruising in M5. DTH is also the field elevation for M9 landings. The last field contains DMN, the Mach number to be sought and held in M5.

Appendix A

SUBROUTINE FLYIT3 LISTING

A-1

26

1:C SUBROUTINE FLYIT3 (MAIN PROGRAM)
 2:C INPUT INSTRUCTIONS
 3:C A COMPLETE DATA DECK CONSISTS OF 3 CARDS PER TRAJECTORY
 4:C FIRST DATA CARD - TRAJECTORY PHASE SEQUENCE IN 1011 FORMAT, M VALUES
 5:C M=1 RUNWAY TAKE-OFF AT MAX POWER FROM FIELD ELEVATION XLH
 6:C M=2 AIR LAUNCH AT XLH ALTITUDE, XLM MACH, XLFEE FLIGHT PATH ANGLE, AND
 7:C CLIMB AT CLMN MACH DFEEC FLIGHT PATH ANGLE AND CONTINUOUSLY REDUCE
 8:C FLIGHT PATH ANGLE IF NECESSARY TO MAINTAIN SPEED.
 9:C M=3 CRUISE AT DCH ALTITUDE AND CMN MACH UNTIL RC RANGE IS REACHED
 10:C OR FUEL IS EXHAUSTED
 11:C M=4 DIVE AT -DFEEDD FLIGHT PATH ANGLE UNTIL PULL-UP IS INITIATED
 12:C M=5 PULL-OUT FROM DIVE AT GPU LOAD FACTOR AND CRUISE AT DTH ALTITUDE AND
 13:C DMN MACH
 14:C M=6 FLY AT CONSTANT VELOCITY UNTIL DCH ALTITUDE OR RC RANGE IS REACHED
 15:C OR IMPACT
 16:C M=7 BOOSTER LAUNCH WITH FLIGHT PATH ANGLE DFEEC FIRST 100 FEET
 17:C M=8 FLY AT BODY ANGLE BAC OR BAD DEGREES UNTIL DCH IS REACHED
 18:C M=9 APPROACH TO LANDING AT GLIDE SLOPE DFEEDD, RUNWAY ELEVATION DTH,
 19:C APPROACH SPEED DMN MACH
 20:C M=10 DIRECTS THE VEHICLE TO FLY ALONG THE RADAR HORIZON WHEN THE
 21:C HORIZON IS INTERCEPTED IN M=3 CRUISE. TARGET ANTENNA IS ASSUMED
 22:C TO BE AT 100 FEET ABOVE SEA LEVEL. RANGE TO TARGET MUST BE INPUT
 23:C AS RC (NMI).
 24:C IF USED AT ALL, M=1 AND M=7 MUST BE FIRST IN THE SEQUENCE.
 25:C IF USED AT ALL, M=9 WILL BE LAST IN THE SEQUENCE.
 26:C NOT M VALUE MAY BE USED MORE THAN ONCE IN A TRAJECTORY EXCEPT 2,3,4,6,8.
 27:C M=4 MUST BE USED IN THE SEQUENCE 45, OR BE THE LAST IN THE SEQUENCE.
 28:C M=10 IF USED AT ALL MUST BE LAST IN THE SEQUENCE
 29:C REMAINDER OF FIRST CARD IN FORMAT 815. --
 30:C BOOSTER MULTIPLIER
 31:C ATMOSPHERE - 0 FOR STD, 1 FOR HOT DAY, 2 FOR COLD DAY
 32:C AERODYNAMICS - SUBROUTINE NUMBER FROM AERO LIBRARY
 33:C BOOST PROPULSION - SUBROUTINE NUMBER FROM BOOSTER LIBRARY - 0 IF NONE
 34:C SUSTAIN PROPULSION - SUBROUTINE NUMBER FROM SUSTAINER LIBRARY - 0 IF
 35:C NO SUSTAINER
 36:C OUTPUT OPTIONS - 0 GIVES BRIEF FORMAT (REPEATS DATA CARD ENTRIES)
 37:C 1 GIVES FULL PRINTER LIST OF INPUT DATA
 38:C 2 GIVES OPTION 1 PLUS A PLOT OF THE TRAJECTORY
 39:C 3 INDICATES DEMAND TERMINAL OUTPUT FORMAT (FULL LIST)
 40:C 4 INDICATES SHORT FORM DEMAND TERMINAL OUTPUT
 41:C 5 INDICATES OPTION 4 PLUS TRAJECTORY PLOT
 42:C CLOSER-LOOK OPTION - IF FINER PRINT RESOLUTION DESIRED, PUNCH 1 IN 45
 43:C RANGE OUTPUT WILL BE IN FEET IF 1 IS PUNCHED IN 50
 44:C SECOND DATA CARD - MISSILE LAUNCH WEIGHT INCLUDING BOOSTER, MISSILE EMPTY
 45:C WEIGHT INCLUDING UNUSEABLE FUEL, MISSILE REFERENCE AREA IN SQ FT,
 46:C ANGLE OF ATTACK LIMIT IN DEGREES, ENGINE INLET CAPTURE AREA IN SQ FT,
 47:C SUSTAINER THRUST MULTIPLIER, LOAD FACTOR TO BE USED IN ANY PULL-UP
 48:C MANEUVER, LAUNCH ALTITUDE, LAUNCH MACH NUMBER, LAUNCH FLIGHT PATH ANGLE
 49:C - ALL IN FORMAT 12F5.0.
 50:C THIRD DATA CARD - DESIRED CLIMB FLIGHT PATH ANGLE, CLIMB MACH NUMBER, CLIMB

FLYIT3 CONTINUED

```

51:C BODY ANGLE, DIVE BODY ANGLE, CRUISE ALTITUDE, CRUISE MACH NUMBER, CRUISE
52:C RANGE, DIVE ANGLE, DIVE MACH NUMBER, DASH ALTITUDE, DASH MACH NUMBER
53:C - ALL IN FORMAT 12F5.0.
54:C INPUT DATA UNITS IN DEGREES, THOUSANDS OF FEET, SQUARE FEET, MACH NUMBER,
55:C NAUTICAL MILES, G'S, POUNDS
56:C MAIN PROGRAM
57:C
58: DIMENSION M(10),PP(2000),RS(900),HS(900),RSFT(400),HSLD(400)
59: COMMON W,W0,WE,RO,AREF,CLAR,ALPHA,ALPHA1,ALPL,V,VR,VH,Q,THR,FEED,

Appendix I
TRAJECTORY EXAMPLES

Five example trajectories are illustrated in this appendix. Each is represented by a plot and demand mode output format. Each plot is annotated so that the user can correlate the program's response to the input data.

The output column labeled CDX can contain either the total zero-lift drag coefficient (CDO), or the inlet spillage drag coefficient. Since both coefficients will be based on AREF, CDO will be a number in the range 0.15 - 1.5, and spillage drag coefficient will be considerably smaller (0 - 0.1). This difference in magnitude should provide for discrimination.
